29 Network management is the task of managing the access to networks. In other  
30 words, deciding when and through which means to connect to the internet. In  
31 an IVI context this task is affected by several conflicting requirements. Connec-  
32 tivity may be spotty at times, with tunnels, high speed causing WiFi networks  
33 to come and go quickly, low cell phone signal strength, and so on. On the other  
34 hand, potentially good connectivity while parked, since the user might have high  
35 quality WiFi at the office and at home. Network Management will be discussed  
36 in [Network management](#).

37 Online and cellular-based real-time communications, including chatting, voice  
38 calls, VoIP and video calls are covered in [Real-time communications](#).

39 It is very common these days to have people carrying one or more smart devices  
40 with them. People want those smart devices to connect to their in-vehicle  
41 infotainment system for playing audio, importing contacts and also use or share  
42 Internet connections. This is discussed in [Tethering from mobile devices](#).

43 The main medium used for inter-device communication, Bluetooth, and its var-

44 ious profiles are discussed in [Bluetooth support](#). A brief discussion of using  
45 GPS to enhance network management and about the GeoClue framework are  
46 the subject of [Global Positioning System \(GPS\)](#).

47 Contacts management is covered by a separate document. Integration with  
48 other devices by means other than Bluetooth and USB mass-storage, such as  
49 reading songs off of an iPod is the topic discussed in [Media downloading](#).

## 50 **Network management**

51 The main goals of network management in an IVI system are to make sure the  
52 best connection is being used at all times while providing enough information  
53 to applications so that they can apply reasonable policies. For example, the  
54 IVI system should be able to fall-back to a metered 3G connection when an  
55 active WiFi connection is lost (because, say, the user drives their car out of  
56 their garage). In addition, big downloads should be paused in such a case; these  
57 would only be resumed when on an unmetered connection, to avoid significant  
58 charges on the user's phone bill.

59 [ConnMan](#)<sup>1</sup> is the central piece of the network management system being consid-  
60 ered for Apertis. It is focused on mobile use cases, provides good flexibility and  
61 features that allow implementation of the use cases mentioned above. [oFono](#)<sup>2</sup> is  
62 the de-facto standard when it comes to cellular connections and related features,  
63 and it is able to work in cooperation with ConnMan.

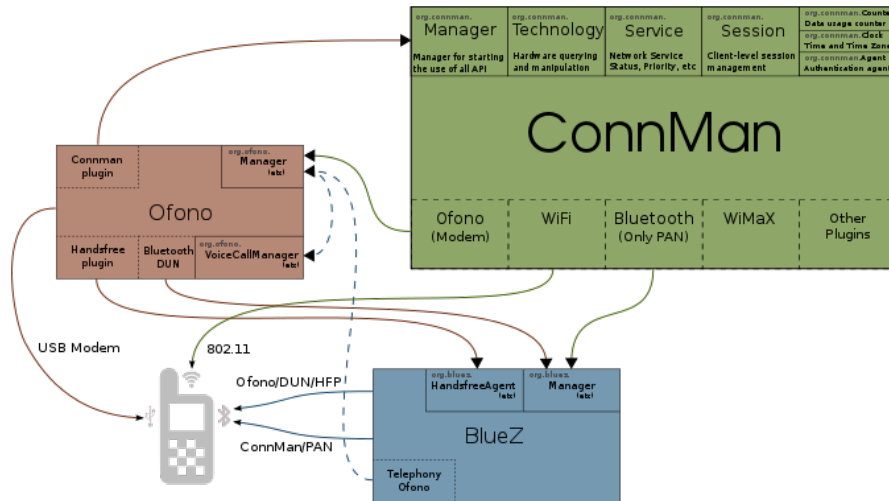

64 To complete the functionality expected from a modern network management  
65 framework, Bluetooth integration is also important. [BlueZ](#)<sup>3</sup> is used to provide  
66 that integration, allowing ConnMan to use Bluetooth devices to go online. Il-  
67 lustration has a schematic view of the interactions among these frameworks.

<sup>2</sup><http://oFono.org/>

<sup>3</sup><http://bluez.org/>

68

## 69 Switching to a different connection

70 There are very specific requirements about how and when the system should  
 71 switch from an active Internet connection to a newly-available one. ConnMan  
 72 developers are working in a infrastructure for policy plugins. Collabora believes  
 73 this new infrastructure can be used to implement the policies required to satisfy  
 74 the requirements.

75 The two main concerns are that the system should not switch to a WiFi network  
 76 that just became available, since that may just be an open network in a café  
 77 the car is passing by, but that it should also take advantage of good known  
 78 connections when they are available.

79 ConnMan provides several facilities to gather information useful for such policy  
 80 decisions. For instance, a network that has been manually selected by the user  
 81 will have the Favorite property set to true.

82 That can be used to implement a policy of never automatically migrating to  
 83 open WiFi networks that are detected, unless it has been successfully used  
 84 before. This would guarantee that the system is able to switch automatically to  
 85 relevant networks without running into the problem of trying to associate with  
 86 the every open network it passes by.

87 Because connections may be lost or replaced by a better connection by Conn-  
 88 Man, applications need to be aware that their session may go away at any time,  
 89 and be able to recover from that. When a connection change happens, Conn-  
 90 Man will emit a D-Bus signal, and applications may need to drop connections  
 91 they have started and restart whatever they were doing.

92 A concrete example would be the email application that is connected to an  
 93 IMAPx server; when a connection change happens, the application gets notified

94 the connection it was using has gone away, so it drops all connections it had with  
95 the IMAPx server. If the new connection satisfies the requirements specified by  
96 the email client on its ConnMan session, it gets a “now online” notification and  
97 reconnects to the server.

## 98 **Application requirements and expressing preferences**

99 One very important characteristic of Apertis is that its Internet connectivity  
100 will vary a lot – going from a high speed WiFi network to a slow, unreliable,  
101 metered GSM connection and back is a common scenario, as discussed in the  
102 previous section. It may also be required that a particular type of connection  
103 be established to accommodate the needs of some applications.

104 ConnMan has a feature called Sessions. What that feature provides is a way for  
105 applications to tell ConnMan what they expect from an Internet connection,  
106 and get from ConnMan a network connection status that is relative to those  
107 requirements.

108 For instance, an application that downloads podcasts may have a policy that  
109 it would only perform the downloads when on WiFi. This application would  
110 create a session with ConnMan, and specify settings that ConnMan uses to  
111 decide whether that session is to be considered online or not.

112 The main settings are the **AllowedBearers** and **ConnectionType**. The first  
113 of these specifies which kinds of connections are allowed for the type of traffic  
114 this application intends to do. It is a simple list that specifies the preferred  
115 connection methods, such as, [**cellular, wifi, bluetooth**], which would specify  
116 a preference of cellular connection over both WiFi and Bluetooth .

117 A special “\*” bearer can be used to specify all bearers, which makes it easy  
118 to specify preference for one over all others, which will be treated as equiva-  
119 lent. When one of the connections allowed for an application comes online, the  
120 sessions is declared to be online. When a change happens on a Session setting  
121 ConnMan updates the application with the new values for the changed settings.

122 The second, **ConnectionType**, is used by the application to tell ConnMan if  
123 a connection wants to be online or if local connectivity is enough. Local connec-  
124 tivity means only connectivity in the internal network is needed, for example,  
125 an application may want to exchange data with other devices inside the same  
126 network. There is not much use for this setting in Apertis.

127 An application can have more than one ConnMan session at the same time,  
128 allowing applications to specify multiple policies and preferences, and perform  
129 work according to what is actually available. In addition to these three settings  
130 discussed here, ConnMan also provides several settings that can be used to  
131 customize how both sessions and the system deal with [networking][connman-  
132 networking].

133 Note that the Session API is still in a experimental state and its implementation

134 and API are changing rapidly. This means both that it cannot be considered  
135 a stable part of the API supported by Apertis and that very few existing appli-  
136 cations use it's current form. This should not be a problem for Apertis since  
137 applications are not intended to use ConnMan directly, so a wrapper API can  
138 be specified for the SDK.

### 139 **Binding to the appropriate network interface**

140 ConnMan allows multiple connections to exist at the same time. This might be  
141 useful for various reasons but it also brings some complications with it. First  
142 of all, if an application wants to use a specific connection it needs to explicitly  
143 bind its network usage to the desired network interface.

144 However, binding to a specific interface requires the `NET_RAW` capability<sup>4</sup>  
145 that is not something that regular applications should be allowed to have. A  
146 possible solution would be to also delegate this binding to special application  
147 that has the privileges to do such binding. The viability of such a solution needs  
148 to be properly investigated during the initial development of the feature.

149 Also, keeping in mind the desire to take complexity and control away from  
150 applications it seems desirable to abstract this complexity away to the SDK. The  
151 SDK can provide APIs that wrap ConnMan functionality and handle binding  
152 for the application. This means more Apertis-specific code, however, meaning  
153 less code reuse for existing applications.

### 154 **Connections policies and store applications manifests**

155 As discussed above, some control can be exerted on how ConnMan ranks and  
156 chooses connections by having applications (or a system service on their behalf)  
157 provide ConnMan with a list of their requirements using the Session APIs.

158 It has been made clear that applications from the store should be specifying  
159 their needs as much as possible through the manifest file that will be distributed  
160 along with applications on the app store. For network management this means  
161 specifying the allowed bearers, mainly.

162 The policy plugin mentioned above could use information provided by the appli-  
163 cation manager and application manifest files to decide on what the best policy  
164 to implement is. This would not require changing applications, but limits the  
165 flexibility the developer has to work with.

### 166 **Network-related events and how applications need to behave**

167 For applications that are written to work with ConnMan, two signals are essen-  
168 tial: connection is up, connection is down. When a connection comes up the  
169 application takes the appropriate steps to start whatever its functionality is.

---

<sup>4</sup><http://git.kernel.org/?p=linux/kernel/git/next/linux-next.git;a=blob;f=net/core/sock.c;h=b374899aecb6ea3a8590ae9ccd3e60225561d4;hb=HEAD#1470>

170 An IMAP mail client would at this point connect to the IMAP server, and look  
171 for new messages, a podcast downloader would look for new podcasts to start  
172 downloading or resume any downloads that had previously been started, and so  
173 on.

174 When the connection goes down – even if it’s just being switched from one  
175 connection method to another – any existing IP connections would not work  
176 any more, since the IP address will have changed. The application needs to  
177 close any connections. This means an IMAP mail client would close the sockets  
178 it had open with the IMAP server, a podcast downloader will close the HTTP  
179 or FTP connections, and so on. The connections can be re-established/resumed  
180 in case a new notification comes in that the system is online once more.

181 The following is a potential list of applications and events they will be interested  
182 in handling. As will be seen the events an application needs to handle are  
183 essentially limited to having a connection and not having a connection any  
184 more.

#### 185 **Email client**

- 186 • Connected event
  - 187 – Connect to IMAP server and check for new mail; note that IMAP
  - 188 connections are usually kept alive to receive notifications of new email
  - 189 from the server
  - 190 – Connect to the SMTP server to send any emails stored in the outgoing
  - 191 mail box
- 192 • Disconnected event
  - 193 – Drop IMAP connections
  - 194 – Cancel ongoing loading of email messages
  - 195 – Cancel ongoing sending of email messages, making sure they stay in
  - 196 the outgoing mail box

#### 197 **Media player**

- 198 • Connected event
  - 199 – In case multiple connections are supported, when a faster connection
  - 200 appears switch to it if needed.
  - 201 – If media is being played and previously disconnected, resume buffer-
  - 202 ing
- 203 • Disconnected event
  - 204 – Drop connections

#### 205 **Feed reader**

- 206 • Connected event

- 207           – Begin download of the latest entries
- 208           – If it's a fast connection, begin pre-caching of images and other big
- 209            feed attachments
- 210       • Disconnected event
- 211           – Drop connections

## 212 **Continuing downloads**

213 The HTTP protocol provides clients and servers with the ability of picking up a  
214 transfer from a given point, so that partially downloaded content does not need  
215 to be re-downloaded in full when a connection is dropped and reconnected.  
216 Details about how the protocol supports partial downloads can be found in  
217 [RFC2616](#)<sup>5</sup>.

218 In summary, when picking up a download the client should send a *Range* header  
219 specifying the bytes it wants to download. If the server supports continuing  
220 downloads and the range is acceptable a **206 Partial Content** response will  
221 be sent instead of the usual **200 OK** one. The client can then append the  
222 data to the partially downloaded file. If the server does not reply with a **206**  
223 response, then the file needs to be truncated, since the download will be starting  
224 from scratch.

## 225 **Connectivity policies on Android**

226 Connectivity policies on Android are a way more simpler. The Android system  
227 does not implement any per application configuration on how application should  
228 access the internet (wifi, 3g, etc.).

229 Also Android does not have any mechanism to notify the applications that the  
230 system is online, the applications just get a notification about a Network State  
231 Change and then they have to figure out by themselves if the system is online  
232 by requesting a “route to host”.

233 One of the few network configurations android has is to enable/disable Wi-Fi,  
234 mobile data and roaming allowance globally. Apart from that the user can also  
235 restrict background data usage for each applications in the Global Settings.

## 236 **Real-time communications**

237 The Apertis needs to be well-connected with Internet communication services  
238 such as Google Talk and Skype. [Telepathy](#)<sup>6</sup> provides a framework for enabling  
239 messaging, video and audio calling through many of the existing services, and  
240 more can be supported by developing custom [connection managers](#)<sup>7</sup>.

---

<sup>5</sup><http://www.w3.org/Protocols/rfc2616/rfc2616-sec14.html#sec14.35>

<sup>6</sup><http://telepathy.freedesktop.org/wiki/>

<sup>7</sup><http://telepathy.freedesktop.org/doc/book/sect.connection.connection-manager.html>

241 Telepathy provides a D-Bus API which abstracts away the specific connection  
242 managers allowing a UI to seamlessly support various protocols while only hav-  
243 ing little or no protocol specific knowledge. The fact that Telepathy is imple-  
244 mented as several D-Bus services makes it possible to integrate messaging and  
245 voice features throughout the system.

246 A good example of these are the chat, dialler and address book applications  
247 present on the Nokia N900 and [N9 devices](#)<sup>8</sup>, which use Telepathy to support  
248 messaging, GSM and VoIP Calls using one single user interface, while at the  
249 same time providing ways for the user to choose which protocol they want for  
250 a given conversation.

251 Existing open-source connection managers support messaging through Jabber,  
252 GTalk, Facebook, Live Messenger, and more. Audio and video calls are also  
253 supported over Jabber, GTalk and SIP. See the [Telepathy wiki](#)<sup>9</sup> for more de-  
254 tails. Before deciding on shipping any of these, however, it's important to verify  
255 whether any legal issues may arise, mainly related to trademarks.

256 As discussed before, Telepathy is pluggable, enabling a mix of closed and open-  
257 source connection managers to coexist. This enables OEMs to enable as many  
258 third-party services as desired, requiring for the technical side at most the cre-  
259 ation of a new connection manager.

260 Collabora has been involved in consultancy projects to integrate various propri-  
261 etary backends in the past and is ready to do so again if it is decided to include  
262 support for more protocols. More details about this will be included in reference  
263 produced during the development phase by the documentation team.

## 264 **Traditional Telephony (GSM, SMS)**

265 The system shall support making and receiving calls and sending/receiving text  
266 messages through a paired cell phone. Telepathy has a backend on top of oFono  
267 to make calls and send text messages, which makes it possible to easily have a  
268 single, integrated user interface for both regular phone calls and messages along  
269 with those of online services.

270 Telepathy is focused on messaging and calling; as such, it does not include  
271 GSM/UMTS-specific functionality like signal-strength, data connections, and  
272 so on. Those features are accessible through oFono directly.

## 273 **Tethering from mobile devices**

274 There are six main ways to hop on to a mobile device's Internet connection:

- 275 • WiFi connection for devices that support mobile hotspot

---

<sup>8</sup><http://techprolonged.com/index.php/2011/11/12/nokia-n9-a-complete-walk-through-meego-harmattan-software-and-user-interface-experience/#contacts-calling>

<sup>9</sup><http://telepathy.freedesktop.org/wiki/Protocols%20Support>

- 276 • Using the DUN Bluetooth profile, through oFono
- 277 • Using the PAN Bluetooth profile
- 278 • Using Ethernet over USB
- 279 • Using 3G USB modem
- 280 • Using device-specific proprietary protocols

281 A mobile hotspot feature is becoming more common on mobile devices and, in  
282 a way, taking the place once occupied by Bluetooth for tethering. It is a good  
283 connection method because it is very simple to set up.

284 The PAN profile is supported by ConnMan through BlueZ and DUN also needs  
285 these two components to works plus a extra one, which is oFono. This difference  
286 is due to the fact that the DUN profiles behaves like a modem and thus needs  
287 oFono to handle it. All interactions between BlueZ and the two other daemons,  
288 ConnMan and oFono, are performed using BlueZ's D-Bus interface, and as such  
289 should not cause problems in case is planned to replace BlueZ with a proprietary  
290 counterpart that implements the same interfaces.

291 Note that connecting a phone to the car for tethering over Bluetooth is a process  
292 that requires user intervention: the user needs to first pair the two devices. In  
293 most systems that support connections over the cell phone network the user  
294 is also asked to choose the plan they acquired from their provider from a list,  
295 which will also need to be done for the Apertis; only then the connection will  
296 be made available through ConnMan.

297 Ethernet over USB is supported by Linux using the usbnet driver. Among  
298 device-specific protocols, Apple devices in particular are important. Linux in-  
299 cludes, since version 2.6.34, the [ipheth](#)<sup>10</sup> driver, which enables using Ethernet  
300 over the USB connection for Apple devices. In addition to the driver, pairing  
301 of the device by a user-space program is required. That pairing can be per-  
302 formed either by using the standalone tool provided at the project's web page  
303 or through the tools distributed by the **libimobiledevice** project, discussed in  
304 [Media downloading](#).

305 Collabora believes the three main components discussed here, BlueZ, oFono and  
306 ConnMan are capable of supporting tethering to most mobile devices. Provided  
307 appropriate user interfaces are implemented, ConnMan is able to provide all  
308 requirements regarding having several different phones in the car, including  
309 prioritizing and selecting which one should be used.

## 310 Counting bytes and getting information about bandwidth

311 ConnMan provides an API called **Counters** that is used for tracking how much  
312 traffic has gone through a given connection, and can be used by the network  
313 connections management UI to inform the user about the quantity of data that

---

<sup>10</sup><http://giagio.com/wiki/moin.cgi/iPhoneEthernetDriver>

314 has been transmitted. The counters are per-connection and are automatically  
315 updated with the information by ConnMan.

316 oFono also provides the **CallMeter** API for tracking how much conversation  
317 time is still available for a GSM phone, using data from the SIM. oFono is able  
318 to emit a warning when the limits are close to be reached.

319 For measuring bandwidth there is no convenient API at the moment. Clients can  
320 register a counter and specify an update interval, but ConnMan advises against  
321 using that API for tracking time. A more robust and correct implementation  
322 would be to have applications and services that care about that information  
323 track the RX/TX bytes and run a timer of their own to estimate how much  
324 bandwidth is being used at a given point in time.

325 It is important to note that tracking connection quality taking in account used  
326 bandwidth (and possible other variables as connection latency and available  
327 bandwidth) is not a easy task. Usually those variables doesn't give enough  
328 information to decide which connection has the better quality.

## 329 **Providing Internet connectivity to other devices**

330 In case the Apertis has Internet connectivity itself, it should be able to share it  
331 with other devices through either Bluetooth or WiFi.

332 ConnMan supports sharing the current Internet connection by using the WiFi  
333 interface in master mode or via Bluetooth PAN profile, becoming an access  
334 point that other devices can connect to. This is done by turning on tethering  
335 mode on WiFi or Bluetooth.

336 See the tethering properties at the bottom of [http://git.kernel.org/  
337 ?p=network/connman/connman.git;a=blob;f=doc/technology-api.  
338 txt;h=851d5ea629975c9c82d86c7863aaab2997485c34;hb=HEAD](http://git.kernel.org/?p=network/connman/connman.git;a=blob;f=doc/technology-api.txt;h=851d5ea629975c9c82d86c7863aaab2997485c34;hb=HEAD)

339 As is the case with other features, this needs proper UI to be created to let the  
340 user turn the tethering on as well as specify the desired SSID and pass-phrase for  
341 WiFi, or to pair the Bluetooth devices. In order for this feature to be provided,  
342 the driver for the wireless chip used in the development board needs to support  
343 the master mode.

## 344 **A web server to provide information**

345 Apertis will have a web server running internally to provide information about  
346 the system and the car for access by smart phones. Collabora's working as-  
347 sumption is the server will be available to devices that connect to the WiFi  
348 or Bluetooth hotspot provided by the system, regardless of whether it is being  
349 used to provide Internet connectivity to the devices or not. Libwebsockets can  
350 be used to write a solution for web server.

351 For users to access the web server, the manual of the device will contain a

352 specific URI, and the DNS server provided by the device will resolve the name  
353 to the address the system has in the address space used by its DHCP.

## 354 **Bluetooth support**

355 The automotive space is by far the biggest user of Bluetooth for communications  
356 between the car and external devices, such as phones, tablets, notebooks, and  
357 so on. Plans have been stated to acquire a proprietary solution and supplement  
358 BlueZ in the apertis.

359 That solution sits in between applications that use BlueZ and the BlueZ daemon,  
360 and adapts requests to make sure specific device quirks are satisfied.

361 BlueZ is currently a fairly complete Bluetooth stack, and has support for all of  
362 the major [Bluetooth profiles](#)<sup>11</sup>. It's important to note, however, that applica-  
363 tions need to be written to use the Bluetooth infrastructure for connecting to  
364 mobile devices for music playing, remote control, file transfer, downloading of  
365 contacts and tethering.

366 For other Bluetooth profiles, the ones supported by BlueZ will be provided,  
367 development of support for more profiles is out of scope for this project. The  
368 list of Bluetooth profiles bellow was extracted from the Apertis Feature List  
369 document, and information is provided on the general level of support provided  
370 by BlueZ. For a more detailed list of existing support and gaps, Collabora would  
371 require a more detailed list of requirements.

372 When it comes to pairing support BlueZ supports both Legacy Pairing (PIN  
373 entry, many old devices only support this type of pairing) and Secure Simple  
374 Pairing (Numeric Comparison).

## 375 **Bluetooth 3.0, 4.0, High Speed, L2CAP, SDP, RFCOMM**

376 BlueZ currently supports the both Bluetooth 3.0 and 4.0 core specification.  
377 However, High Speed support through 802.11 AMP is still under development,  
378 so it is not currently supported. The Bluetooth core support provided by BlueZ  
379 includes Logical Link and Control Adaptation Protocol (**L2CAP**), Service Dis-  
380 covery Protocol (**SDP**) and Radio Frequency Communications (**RFCOMM**).

## 381 **SPP**

382 The Serial Port Profile (**SPP**) 1.1 is supported by BlueZ. The Serial Port Profile  
383 allows emulation of serial ports over a Bluetooth link.

## 384 **PAN and DUN**

385 As discussed in sections [Network management](#) and [Tethering from mobile de-](#)  
386 [vices](#), BlueZ provides support for the Personal Area Networking (**PAN**) profile

---

<sup>11</sup><http://www.bluez.org/profiles/>

387 both in the NAP role (BlueZ acting as connection provider) or PANU role  
388 (BlueZ using a internet connection over Bluetooth).

389 There is support for the DUN profile. The Client role is implemented by an  
390 extra oFono's daemon and can be used to connect to devices providing internet  
391 connection.

392 There is also support for the server role of the Dial-up Networking (**DUN**)  
393 profiles, which can be used with oFono and ConnMan to provide Internet con-  
394 nection to an external device. However current implementation only supports  
395 sharing a DUN connection only if the device has a GPRS data connection ac-  
396 tive. Collabora thinks that lack the support for DUN server won't be a problem.  
397 DUN is rapidly being replaces by the PAN profile.

#### 398 **GOEP, OBEX**

399 The Generic Object Exchange Profile (**GOEP**) and Object Exchange Proto-  
400 col (**OBEX**) are also supported by BlueZ. They enable file exchange between  
401 Bluetooth-capable devices and the Apertis system.

#### 402 **PBAP, MAP, OPP, SYNCH**

403 The Phone Book Access Profile (**PBAP**) is supported by BlueZ, and can be used  
404 for downloading contacts from the external devices. There is also support for  
405 Object Push Profile (**OPP**), used for transferring vCards and vCalendars. Fi-  
406 nally, BlueZ also supports the 1.0 version of the Message Access Profile (**MAP**)  
407 version 1.0 in the client role\*\*,\*\* which can be used to download SMS messages  
408 and email from a phone onto the Apertis system, however support to upload  
409 delete and mark messages as read/unread is lacking at the moment.

410 Note that, although BlueZ includes support for these profiles, it's up to ap-  
411 plications on the system to make use of the framework to provide the actual  
412 features. For instance, the contacts application needs to talk to BlueZ to per-  
413 form the phone book download.

414 There is currently no support for the Synchronization Profile (**SYNCH**) profile.  
415 Collabora's current understanding is this does not pose a problem for the use  
416 cases planned, since only support for download of the contacts is required.

417 For more information on the specific use-cases, problems and proposed solutions  
418 regarding contacts in the Apertis system refer to the Contacts design document  
419 prepared by Collabora.

#### 420 **AVRCP, A2DP, VDP**

421 These profiles are used to communicate with devices that are able to reproduce  
422 multimedia content and/or control media playing remotely.

423 BlueZ supports the Audio/Video Remote Control Profile 1.0 (**AVRCP**) in the  
424 controller role, but it only supports the two commands at the moment: Volume

425 Down and Volume Up. Collabora recommends the development of the missing  
426 features for AVRCP 1.0 version and also support for the 1.4 version, which is not  
427 yet supported by upstream. This would provide metadata information about  
428 the media and folder browsing support.

429 When acting as a controller, an application needs to provide the user with an  
430 interface for inputting commands. Collabora will provide sample code for an  
431 application acting on the controller role.

432 Also included is support for acting as sink for the Advanced Audio Distribu-  
433 tion Profile (**A2DP**) version 1.2, using PulseAudio to provide audio routing.  
434 When the device starts to send an A2DP stream to Apertis PulseAudio will  
435 automatically make it available as an output device.

436 PulseAudio has a module that can automatically redirect streams to new output  
437 devices. However, for systems with complex requirements for audio routing it's  
438 probably a better idea to have a system daemon or application managing that;  
439 the car system interface D-Bus daemon is one viable candidate.

440 The Video Distribution Profile (**VDP**) is not yet supported

#### 441 **HFP**

442 The Hands-Free Profile (**HFP**) version 1.6 is supported by BlueZ. Hands-free is  
443 the technology that allows making phone calls with voice commands, and having  
444 audio routed from the phone to a different device, such as the Apertis system  
445 which can then play it to the car speakers, for instance. The BlueZ framework,  
446 along with oFono, can be used to add hands-free support to the system. Wide  
447 Band Speech – high quality audio for calls, though, is not yet supported by  
448 BlueZ.

449 After a SIM-enabled device in Audio Gateway mode has been paired with BlueZ,  
450 PulseAudio will be able to use it as source and sink through its Bluetooth module  
451 and route streams from the car's microphone to the phone and the audio from  
452 the call to the car's speakers. In this case BlueZ acts as in the Hands-free role.

453 The application which handles the calls can use PulseAudio APIs to control the  
454 volume of the source and sink streams, and should set the **filter.want** property  
455 of the [PulseAudio streams](#)<sup>12</sup> to let PulseAudio know echo cancellation should  
456 be used.

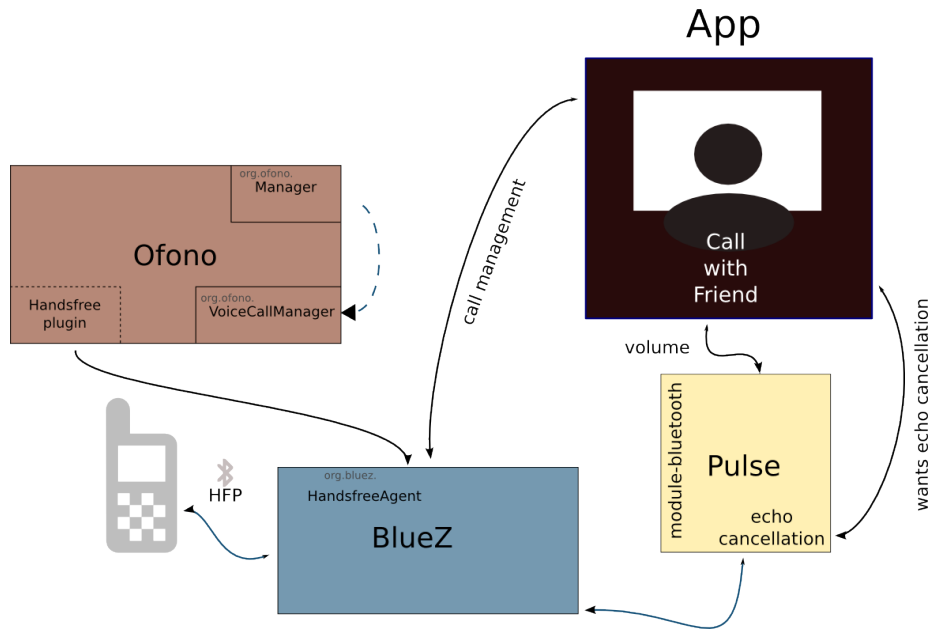

457 This will cause PulseAudio to automatically load the echo cancellation module.  
458 The echo cancellation module can also contain a noise cancellation sub-module.  
459 PulseAudio ships with an Open Source sub-module based on speex for echo  
460 cancellation, but it can be replaced by custom or proprietary modules if required,  
461 which was the course chosen by Nokia for its phones, for instance. The same goes

---

<sup>12</sup>[http://freedesktop.org/software/pulseaudio/doxygen/proplist\\_8h.html#a87c586045175fa05e28e6ee1cbaac4de](http://freedesktop.org/software/pulseaudio/doxygen/proplist_8h.html#a87c586045175fa05e28e6ee1cbaac4de)

462 for the noise cancellation sub-module, it can be easily replaced by an proprietary  
463 noise cancellation solution just by rewriting the sub-module.

464 The diagram in Illustration shows how the various pieces of such a set-up are  
465 related.

466

## 467 HSP

468 Currently BlueZ has no support for the Headset Profile (**HSP**). Collabora rec-  
469ommends it be supported, but that would require development of the feature.  
470 VoIP applications rely on HSP to operate calls over Bluetooth, It is also im-  
471portant to mention that older phones only support the HSP profile for phone  
472calls.

## 473 GSM 07.07 AT-commands

474 oFono has support for most of the GSM 07.07 AT command set. It is through  
475the AT command set that we control the phone in the HFP profile.

## 476 GNSS

477 The Global Navigation Satellite System Profile is currently not supported by  
478 BlueZ, nonetheless adding support would be simple in the BlueZ side. For this  
479 profile, BlueZ would only provide the Bluetooth connection handling, all the  
480 navigation specific data would be passed to the GPS specific application to  
481 handle it.

## 482 Global Positioning System (GPS)

483 The Apertis platform provided by Collabora will include the GeoClue geoloca-  
484 tion framework. [GeoClue](#)<sup>13</sup> provides a D-Bus service that can be queried to  
485 establish the current location of the system with configurable accuracy. Geo-  
486 Clue is able to use the GPS from the system to provide very accurate location  
487 information.

488 This technology will be used, for instance, to power the existing GeoLocation  
489 implementation of the WebKit-Clutter library. The service can be made avail-  
490 able for use by store apps, potentially including selective restrictions on the  
491 accuracy each app can query. This should be discussed and specified during the  
492 development phase.

493 The connectivity considerations document discusses using GPS data for predict-  
494 ing connectivity conditions, and pre-emptively switching to a different connec-  
495 tion before entering an area with bad coverage, for instance. This seems to be  
496 a risky strategy unless very up-to-date and very extensive data are accessible  
497 to the system at all times. In any case, the GeoClue framework could serve the  
498 purpose of providing the location information from the GPS.

499 One additional advantage of using GeoClue is it supports using different  
500 providers for its information like cell towers through oFono-based gsmloc, WiFi  
501 networks through integration with ConnMan, IP addresses through HostIP,  
502 and so on.

503 Note that HostIP is essentially useless for mobile use cases, since it tries to use  
504 the IP address as an indication of the location, but that is not very accurate in  
505 general and for mobile specifically

506       A somewhat outdated list: [http://www.freedesktop.org/wiki/  
507       Software/GeoClue/Providers](http://www.freedesktop.org/wiki/Software/GeoClue/Providers)

508 Those could be useful to provide location information with coarse accuracy for  
509 applications such as the web browser with no need for turning the GPS on or  
510 for systems with no GPS hardware. If only GPS matters, and tighter control is  
511 required, Collabora can support using the GPS service directly through [gpsd](#)<sup>14</sup>  
512 or [gypsy](#)<sup>15</sup>.

513 If different accuracy levels want to be defined that the store application can use,  
514 different permissions for GPS access can be created representing the different  
515 levels of accuracy. These permissions would be specified in the application's  
516 manifest and prompted to the user at the moment the user authorizes the in-  
517 stallation of an application. Refer to the Applications design for more details  
518 on this.

## 519 Media Downloading

520 This chapter discusses how communication with various devices is made to pro-  
521 vide the Apertis system with ways of downloading media from them. For more  
522 detailed information on use cases, requirements, problems and solutions refer  
523 to the Media Management design document (sometimes called the Media and  
524 Indexing design) prepared by Collabora.

525 In general media will be brought into the system through USB sticks, mobile  
526 devices and online sources. USB sticks are mounted using the USB mass-storage  
527 support. Most USB sticks use the VFAT file system, which is, unfortunately,  
528 patent-encumbered and has been used in the past by Microsoft to promote  
529 law suites against companies shipping devices that support the file system, see  
530 <http://www.groklaw.net/article.php?story=20090401152339514>.

531 When considering communication with specific devices the ones that stand out  
532 are the Apple devices, which are both very well-known and have widespread  
533 usage. This document discusses the Open Source tools that are currently the  
534 state of the art for communicating with Apple devices but does not specifically  
535 recommend their usage.

536 The [libimobiledevice](#)<sup>16</sup> suite is the state of the art on Open Source libraries and  
537 tools for accessing Apple devices. It implements the protocols used for com-  
538 munication with Apple's iPhone, iPad, iPod Touch and TV products, covering  
539 almost all available functionality, including downloading of music and video,  
540 when used in conjunction with libgpod of the gtkpod project<sup>22</sup>. Its pairing tool  
541 is also a requirement for using the ipheth driver mentioned before.

542 The project is a community effort and although it does not require the devices  
543 to be jail-broken, it's not supported by Apple, which means the protocol is  
544 reverse-engineered and often lags behind recent Apple releases. As an example,  
545 iOS 5 support has only recently (22/03/2012) seen the light of day in a release.  
546 Despite these shortcomings, the suite would provide the technical means for  
547 writing the applications that interact with Apple products.

548 Microsoft has also developed a protocol for media exchange called Media Trans-  
549 fer Protocol (MTP). This protocol has been standardized and is currently pub-  
550 lished by the [USB implementers forum](#)<sup>17</sup>. A LGPL-licensed library exists that  
551 supports the *Initiator* side of the communication, meaning it is able to access  
552 media on devices that support the MTP *Responder* side: [libmtp](#)<sup>18</sup>. The libmtp  
553 library is currently shipped as a part of Ubuntu and can be provided in the  
554 Apertis middleware platform to be used to implement applications. Note that  
555 as is the case for Apple devices, Collabora is unable to provide legal counselling  
556 about the use of libmtp.

<sup>18</sup><http://libmtp.sourceforge.net/>

557 **UPnP**

558 Universal Plug and Play (UPnP<sup>19</sup>) is a protocol used for discovering and brows-  
559 ing multimedia content made available by media centers. This protocol will  
560 be supported by the Apertis middleware platform using the gupnp library. For  
561 more information about this please see the Media Management design document  
562 (sometimes referred to as Media/Indexing design).
